1 Our project

Our mobile application is called PERDRiX. It connects someone who has found an item on campus with the person who lost it. We realized that our application addressed a genuine need, given the many messages about found or lost items received every day in our X23 class WhatsApp group.

Our application also aims to extend this connection service to campus residents who are not in the X23 class, such as X22 and X24 students, Master's students, and Bachelor's students.

2 Project features

PERDRiX must provide four major features:

- Users must be able to create an account to access the application and then edit their personal information within the application.
- Users must be able to post listings when they find an item by entering the relevant information and uploading a photo of it. They must also be able to delete their posts afterward.
- Users must be able to browse all posts on the platform and then contact the person who created the post. Users must complete a brief verification to ensure that the item truly belongs to them.
- Once contact has been established, users must be able to send messages to one another.

3 Project software architecture

3.1 Client architecture

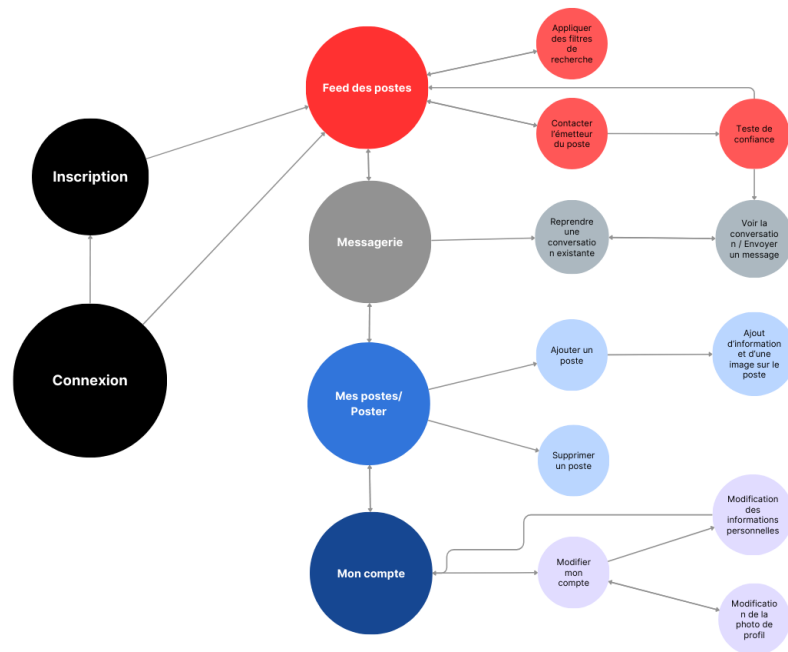

Figure 2: Client architecture

The four major features are represented by four branches in distinct colors.

3.2 Database architecture

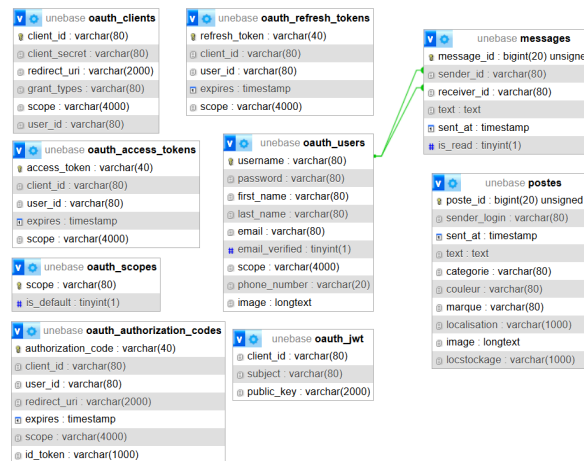

Figure 3: Database architecture

The database contains both the OAuth tables required for account creation and authentication, and the "posts" and "messages" tables. As their names suggest, these store each user's posts and the messages exchanged between users. The "messages" table is therefore linked to the "oauth_users" table through the identifiers of the users who send and receive each message.

4 Information about the code

4.1 Code sourced online

We primarily used Bootstrap code to create the templates. For JavaScript, we occasionally used ChatGPT to identify errors when the code did not work. Finally, we used CSS documentation to make substantial changes to our application's style, particularly its typeface.

4.2 Installed Cordova plugins

The following plugins were installed. The geolocation plugin is not used in this version of the application because, unfortunately, we did not have time to add a map that would have allowed users to provide the location where they stored the item or their own location.

- cordova-plugin-camera 8.0.0 "Camera"
- cordova-plugin-file 8.1.2 "File"
- cordova-plugin-geolocation 5.0.0 "Geolocation"
- cordova-plugin-keyboard 1.2.0 "Keyboard"
- cordova-plugin-splashscreen 6.0.1 "Splashscreen"

5 Accessing the application

5.1 How to install our application

There are no particular difficulties involved in installing our application: since we did not publish it in the app stores, we simply installed it using Cordova.

5.2 Login credentials

The following five accounts are currently in the database:

Login	Password
philibert	mdp
titouan_salin	mdp
Harry	mdp
CA	mdp
Dark Vador	mdp
